

Synchronous Buck Controller

FEATURES

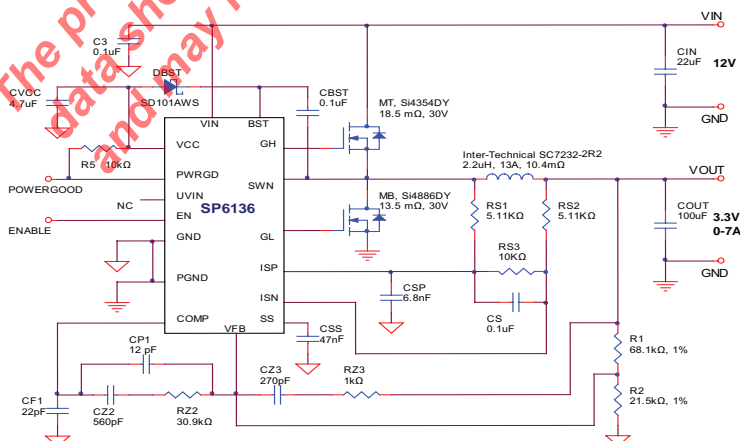

- 5V to 24V Input step down converter
- Up to 7A output in a small form factor
- Highly integrated design, minimal components
- UVLO Detects Both V_{CC} and V_{IN}
- Overcurrent circuit protection with auto-restart
- Power Good Output, ENABLE Input
- Maximum Controllable Duty Cycle Ratio up to 92%
- Wide BW amp allows Type II or III compensation
- Programmable Soft Start
- Fast Transient Response
- Available in Lead Free, RoHS Compliant 16-Pin QFN package
- External Driver Enable/Disable
- U.S. Patent #6,922,041

DESCRIPTION

The SP6136 is a synchronous step-down switching regulator controller optimized for high efficiency. The part is designed to be especially attractive for single supply step down conversion from 5V to 24V. The SP6136 is designed to drive a pair of external NFETs using a fixed 600 KHz frequency, PWM voltage mode architecture. Protection features include UVLO, thermal shutdown, output short circuit protection, and overcurrent protection with auto restart. The device also features a PWRGD output and an enable input. The SP6136 is available in a space saving 16-pin QFN and offers excellent thermal performance.

TYPICAL APPLICATION CIRCUIT

Note: Die attach paddle is internally connected to GND.

ABSOLUTE MAXIMUM RATINGS

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections of the specifications below is not implied. Exposure to absolute maximum rating conditions for extended periods of time may affect reliability.

V _{CC}	6V
V _{IN}	24.5V
BST	30V
BST-SWN	7V
SWN	-2V to 24V
GH	-0.3V to BST+0.3V
GH-SWN	6V

All other pins.....-0.3V to V_{CC}+0.3V

Peak Output Current < 10μs	
GH, GL	2A
Storage Temperature	-65°C to 150°C
Power Dissipation	1W
ESD Rating	2kV HBM
Thermal Resistance	41.9°C/W

ELECTRICAL SPECIFICATIONS

Unless otherwise specified: -40°C < T_{AMB} < 85°C, 4.5V < V_{CC} < 5.5V, BST=V_{CC}, SWN = GND = PGND = 0.0V, UV_{IN} = 3.0V, CV_{CC} = 10μF, C_{COMP} = 0.1μF, CGH = CGL = 3.3nF, C_{SS} = 50nF, R_{PWRGD} = 10KΩ.

PARAMETER	MIN	TYP	MAX	UNITS	CONDITIONS
QUIESCENT CURRENT

BLOCK DIAGRAM

PIN #	PIN NAME	DESCRIPTION
1	GL	High current driver output for the low side NFET switch. It is always low if GH is high or during a fault. Resistor pull down ensures low state at low voltage.
2	PGND	Ground Pin. The power circuitry is referenced to this pin. Return separately from other ground traces to the (-) terminal of Cout.
3	GND	Ground pin. The control circuitry of the IC is referenced to this pin.
4	VFB	Feedback Voltage and Short Circuit Detection pin. It is the inverting input of the Error Amplifier and serves as the output voltage feedback point for the Buck Converter. The output voltage is sensed and can be adjusted through an external resistor divider. Whenever VFB drops 0.25V below the positive reference, a short circuit fault is detected and the IC enters hiccup mode.
5	COMP	Output of the Error Amplifier. It is internally connected to the non-inverting input of the PWM comparator. An optimal filter combination is chosen and connected to this pin and either ground or VFB to stabilize the voltage mode loop.
6	EN	Enable Pin. Pulling this pin below 0.4V will place the IC into sleep mode. This pin is internally pulled to VCC with a 1 μ A current source.
7	PWRGD	Power Good Output. This open drain output is pulled low when VOUT is outside of the regulation. Connect an external resistor to pull high.
8	SS	Soft Start/Fault Flag. Connect an external capacitor between SS and GND to set the soft start rate based on the 10 μ A source current. The SS pin is held low via a 1mA (min) current during all fault conditions.
9	ISN	Negative Input for the Sense Comparator. There should be a 60mV offset between PSENSE and NSENSE. Offset accuracy +10%.
10	ISP	Positive Input for the Inductor Current Sense.
11	SWN	Lower supply rail for the GH high-side gate driver. Connect this pin to the switching node at the junction between the two external power MOSFET transistors.
12	GH	High current driver output for the high side NFET switch. It is always low if GL is high or during a fault.
13	BST	High side driver supply pin. Connect BST to the external boost diode and capacitor as shown in the Application Schematic of page 1. High side driver is connected between BST pin and SWN pin.
14	VIN	Supply Input -- supplies power to the internal LDO.
15	UVIN	Under Voltage lock-out for VIN voltage. Internally has a resistor divider from VIN to ground. Can be overridden with external resistors.
16	VCC	Output of the internal LDO. If VIN is less than 5V then Vcc should be powered from an external 5V supply.

Note: Die attach paddle is internally connected to GND.

THEORY OF OPERATION

General Overview

The SP6136 is a fixed frequency, voltage mode, synchronous PWM controller optimized for high efficiency. The part has been designed to be especially attractive for single supply input voltages ranging between 5V and 24V.

The heart of the SP6136 is a wide bandwidth transconductance amplifier designed to accommodate Type II and Type III compensa-

tion schemes. A precision 0.8V reference present on the positive terminal of the error amplifier permits the programming of the output voltage down to 0.8V via the V_{FB} pin. The output of the error amplifier, COMP, compared to a 1V peak-to-peak ramp is responsible for trailing edge PWM control. This voltage ramp and PWM control logic are governed by the internal oscillator that accurately sets the PWM frequency to 600kHz.

The SP6136 contains two unique control features that are very powerful in distributed applications. First, non-synchronous driver control is enabled during start up to prohibit the low side NFET from pulling down the output until the high side NFET has attempted to turn on. Second, a 100% duty cycle timeout ensures that the low side NFET is periodically enhanced during extended periods at 100% duty cycle. This guarantees the synchronized refreshing of the BST capacitor during very large duty ratios.

The SP6136 also contains a number of valuable protection features. A programmable input UVLO allows a user to set the exact value at which the conversion voltage is at a safe point to begin down conversion, and an internal V_{CC} UVLO ensures that the controller itself has enough voltage to properly operate. Other protection features include thermal shutdown and short-circuit detection. In the event that either a thermal, short-circuit, or UVLO fault is detected, the SP6136 is forced into an idle state where the output drivers are held off for a finite period before a re-start is attempted.

Soft Start

“Soft Start” is achieved when a power converter ramps up the output voltage while controlling the magnitude of the input supply source current. In a modern step down converter, ramping up the non-inverting input of the error amplifier controls soft start. As a result, excess source current can be defined as the current required to charge the output capacitor

$$I_{V_{IN}, X} = \frac{C_{OUT} \cdot \Delta V_{OUT}}{\Delta T_{Soft-start}}$$

The SP6136 provides the user with the option to program the soft start rate by tying a capacitor from the SS pin to GND. The selection of this capacitor is based on the $10\mu A$ pull up current present at the SS pin

and the 0.8V reference voltage. Therefore, the excess current source can be redefined as:

$$I_{V_{IN}, X} = C_{OUT} \cdot \Delta V_{OUT} \cdot \frac{10\mu A}{(C_{SS} \times 0.8V)}$$

Hiccup

Upon the detection of a power, thermal, or short-circuit fault, the SP6136 is forced into an idle state for a minimum of 200ms. The SS and COMP pins are immediately pulled low, and the gate drivers are held off for the duration of the timeout period. Power and thermal faults have to be removed before a restart may be attempted, whereas, a short-circuit fault is internally cleared shortly after the fault latch is set. Therefore, a restart attempt is guaranteed every 200ms (typical) as long as the short-circuit condition persists.

A short-circuit detection comparator has also been included in the SP6136 to protect against the accidental short or severe build up of current at the output of the power converter. This comparator constantly monitors the inputs to the error amplifier, and if the V_{FB} pin ever falls more than 250mV (typical) below the voltage reference, a short-circuit fault is set. Because the SS pin overrides the internal 0.8V reference during soft start, the SP6136 is capable of detecting short-circuit faults throughout the duration of soft start as well as in regular operation.

Error Amplifier & Voltage Loop

As stated before, the heart of the SP6136 voltage error loop is a high performance, wide bandwidth transconductance amplifier. Because of the amplifier's current limited ($\pm 100\mu A$) transconductance, there are many ways to compensate the voltage loop or to control the COMP pin externally. If a simple, single pole, single zero response is required, then compensation can be as simple as an RC circuit to ground. If a more complex compensation is required, then the amplifier has enough bandwidth (45° at 4

MHz) and enough gain (60 dB) to run Type III compensation schemes with adequate gain and phase margins at crossover frequencies greater than 200 kHz.

The common mode output of the error amplifier (COMP) is 0.9V to 2.2V. Therefore, the PWM voltage ramp has been set between 1.0V and 2.0V to ensure proper 0% to 100% duty cycle capability. The voltage loop also includes two other very important features. One is a non-synchronous start up mode. Basically, the GL driver cannot turn on unless the GH driver has attempted to turn on or the SS pin has exceeded 1.7V. This feature prevents the controller from “dragging down” the output voltage during startup or in fault modes. The second feature is a 100% duty cycle timeout that ensures synchronized refreshing of the BST capacitor at very high duty ratios. In the event that the GH driver is on for 20 continuous clock cycles, a reset is given to the PWM flip flop half way through the 20th cycle. This forces GL to rise for the remainder of the cycle, in turn refreshing the BST capacitor.

Gate Drivers

The SP6136 contains a pair of powerful 20 Pull-up and 1.5Ω Pull-down drivers. These state-of-the-art drivers are designed to drive an external NFET capable of handling up to 30A. Rise, fall, and non-overlap times have all been minimized to achieve maximum efficiency. All drive pins GH, GL, & SWN are monitored continuously to ensure that only one external NFET is ever on at any given time.

Thermal & Short-Circuit Protection

Because the SP6136 is designed to drive large NFETs running at high current, there is a chance that either the controller or power converter will become too hot. Therefore, an internal thermal shutdown (145°C) has been

included to prevent the IC from malfunctioning at extreme temperatures.

Over-Current Protection

Over-current is detected by monitoring a differential voltage across the output inductor as shown in figure 1. Inputs to an over-current detection comparator, set to trigger at 60 mV nominal, are connected to the inductor as shown.

Since the average voltage sensed by the comparator is equal to the product of inductor current and inductor DC resistance (DCR) then $I_{MAX} = 60\text{mV} / \text{DCR}$. Solving this equation for the specific inductor in circuit 1, $I_{MAX} = 14.6\text{A}$. When I_{MAX} is reached, a 220 ms time-out is initiated, during which top and bottom drivers are turned off. Following the time-out, a restart is attempted. If the fault condition persists, then the time-out is repeated (referred to as hiccup).

Figure 1: Over-current detection circuit

Increasing the Current Limit

If it is desired to set $I_{max} > \{60\text{mV} / \text{DCR}\}$ (in this case larger than 14.6A), then a resistor R_{S3} should be added as shown in figure 2. R_{S3} forms a resistor divider and reduces the voltage seen by the comparator.

$$\text{Since: } \frac{60\text{mV}}{R_{S3}} = \frac{(I_{max} \cdot \text{DCR})}{\{R_{S1} + R_{S2} + R_{S3}\}}$$

Solving for R_{S3} we get:

$$R_{S3} = \frac{[60\text{mV} \cdot (R_{S1} + R_{S2})]}{[(I_{max} \cdot \text{DCR}) - 60\text{mV}]} \quad \text{.....(1)}$$

As an example: if desired I_{MAX} is 17A, then $R_{S3} = 63.4\text{K}\Omega$.

Figure 2- Over-current detection circuit for $I_{max} > 60\text{mV} / \text{DCR}$

Decreasing the Current Limit

If it is required to set $I_{max} < \{60\text{mV} / \text{DCR}\}$, a resistor is added as shown in figure 3. R_{S3} increases the net voltage detected by the current-sense comparator. Voltage at the positive and negative terminal of comparator is given by:

$$V_{SP} = V_{OUT} + (I_{MAX} \cdot \text{DCR})$$

$$V_{SN} = V_{OUT} \cdot \{R_{S3} / (R_{S2} + R_{S3})\}$$

Since the comparator is triggered at 60mV:
 $V_{SP} - V_{SN} = 60\text{ mV}$

Combining the above equations and solving for R_{S3} :

$$R_{S3} =$$

$$R_{S2} \cdot \frac{[V_{OUT} - 60\text{mV} + (I_{MAX} \cdot \text{DCR})]}{60\text{mV} - (I_{MAX} \cdot \text{DCR})} \quad \text{.....(2)}$$

As an example: for I_{MAX} of 12A and V_{OUT} of 3.3V, calculated R_{S3} is $1.5\text{M}\Omega$ (232K Ω standard).

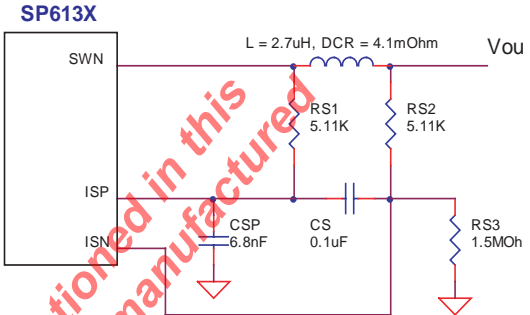

Figure 3- Over-current detection circuit for $I_{MAX} < \{60\text{mV} / \text{DCR}\}$

Power MOSFET Selection

There are four main criterion in selecting Power MOSFETs for buck conversion:

- Voltage rating BV_{DSS}
- On resistance $R_{DS(ON)}$
- Gate-to-drain charge Q_{GD}
- Package type

In order to better illustrate the MOSFET selection process, the following buck converter design example will be used: $V_{IN} = 12\text{V}$, $V_{OUT} = 3.3\text{V}$, $I_{OUT} = 10\text{A}$, $f = 2000\text{KHz}$, $\text{DCR} = 4.5\text{m}\Omega$ (inductor DC resistance), efficiency = 94% and $T_A = 40^\circ\text{C}$.

Select the voltage rating based on maximum input voltage of the converter. A commonly used practice is to specify BV_{DSS} at least twice the maximum converter input voltage. This is done to safeguard against switching transients that may break down the MOSFET. For converters with V_{IN} of less than 10V, a

20V rated MOSFET is sufficient. For converters with 10-15V_{IN}, as in the above example, select a 30V MOSFET.

The calculation of R_{DS(ON)} for Top and Bottom MOSFETs is interrelated and can be done using the following procedure:

1) Calculate the maximum permissible power dissipation P_(DISSIPATION) based on required efficiency. The converter in the above example should deliver an output power P_{OUT} = 3.3V•10A = 33W. For a target efficiency of 94%, input power P_{IN} is given by P_{IN} = P_{OUT}/0.94 = 35.1W. Maximum allowable power dissipation is then:

$$P_{(DISSIPATION)} = P_{IN} - P_{OUT} = 2.1 \text{ W}$$

2) Calculate the total power dissipation in top and bottom MOSFETs P_(MOSFET) by subtracting inductor losses from P_(dissipation) calculated in step 1. To simplify, disregard core losses; then P_L = I_{RMS}² • DCR • 1.4, where 1.4 accounts for the increase in DCR at operating temperature. For the above example P_L = 0.63W. Then:

$$P_{(MOSFET)} = 2.1\text{W} - 0.63\text{W} = 1.47\text{W}$$

3) Calculate R_{DS(ON)} of the bottom MOSFET by allocating 40% of calculated losses to it. 40% dissipation allocation reflects the fact that the top MOSFET has essentially no switching loss. Then P_(BOTTOM) = 0.4X1.47W = 0.59W. R_{DS(ON)} = P/(I_{RMS}² • 1.5) where I_{RMS} = I_{OUT} • {1-(V_{OUT}/V_{IN})}^{0.5} and 1.5 accounts for the increase in R_{DS(ON)} at the operating temperature. Then:

$$R_{DS(ON)} = \frac{P}{\{I_{OUT}^2 \cdot (1 - V_{OUT}/V_{IN})\} \cdot 1.5}$$

$$= 5.4 \Omega.$$

4) Allocate 60% of the calculated losses to the top MOSFET, P_(TOP) = 0.6X1.47 = 0.88W. Assume conduction losses equal to switching losses, then P = 0.5X0.88W = 0.44W. Since it operates at the duty cycle of D=V_{IN}/V_{OUT}; then:

$$R_{DS(ON)} = \frac{P}{I_{OUT}^2 \cdot (V_{OUT}/V_{IN}) \cdot 1.5}$$

$$= 10.7 \Omega.$$

Gate-to-drain charge Q_{GD} for the top MOSFET needs to be specified. A simplified expression for switching losses is:

$$P_s = I_{OUT} \cdot V_{IN} \cdot f \cdot \left\{ \frac{V_{IN}}{dv/dt} + \frac{I_{OUT}}{di/dt} \right\} \dots\dots\dots (3)$$

where dv/dt and di/dt are the rates at which voltage and current transition across the top MOSFET respectively, and f is the switching frequency. Voltage switching time (V_{IN}/dv/dt) is related to Q_{GD}:

$$(V_{IN} / dv/dt) = Q_{GD}/I_G \dots\dots\dots (4)$$

where I_G is Current charging the gate-to-drain capacitance. It can be calculated from:

$$I_G = (V_{DRIVE} - V_{GATE})/R_{DRIVE} \dots\dots\dots (5)$$

where V_{DRIVE} is the drive voltage of the SP6136 top driver minus the drop across the boost diode (approximately 4.5V); V_{GATE} is the top MOSFET's gate voltage corresponding to I_{OUT} (assume 2.5V) and R_{DRIVE} is the internal resistance of the SP6136 top driver (assume 2Ω average for turn-on and turn-off). Substituting these values in equation (5) we get I_G = 1A. Substituting for I_G in equation (4), we get (V_{IN} / dv/dt) = Q_{GD}. Substituting for (V_{IN} / dv/dt) in equation (3) we have:

$$P_s = I_{OUT} \cdot V_{IN} \cdot f \cdot \{Q_{GD} + (I_{OUT} / di/dt)\}$$

Solving for Q_{GD} we get:

$$Q_{GD} = \left\{ \frac{P_s}{I_{OUT} \cdot V_{IN} \cdot f} - \frac{I_{OUT}}{di/dt} \right\} \dots\dots\dots (6)$$

Di/dt is usually limited by parasitic DC-Loop Inductance (L_p) according to di/dt = V_{IN}/L_p.

L_p is due to wiring and PCB traces connecting input capacitors and switching MOSFETs. For typical L_p of 12nH and V_{IN} of 12V, di/dt is 1A/ns. Substituting for di/dt in equation (6) we get $Q_{GD} = 2 \text{ nC}$.

In selecting a package type, the main considerations are cost, power/current handling capability and space constraints. A larger package in general offers higher power and current handling at increased cost. Package selection can be narrowed down by calculating the required junction-to-ambient thermal resistance θ_{JA} :

$$\theta_{JA} = \{T_{J(MAX)} - T_{A(MAX)}\} / P_{(MAX)} \dots\dots\dots (7)$$

Where: $T_{J(MAX)}$ is the die maximum temperature rating, $T_{A(MAX)}$ is maximum ambient temperature, and $P_{(MAX)}$ is maximum power dissipated in the die.

It is common practice to add a guard-band of 25°C to the junction temperature rating. Following this convention, a 150°C rated MOSFET will be designed to operate at 125°C (i.e., $T_{J(MAX)} = 125^\circ\text{C}$). $P_{(MAX)} = 0.88\text{W}$ (from section 4) and $T_{A(MAX)} = 40^\circ\text{C}$ as specified in the design example. Substituting in equation (7) we get $\theta_{JA} = 96.6^\circ\text{C/W}$.

For the top MOSFET, we now have determined the following requirements: $BV_{DSS} = 30\text{V}$, $R_{DS(ON)} = 10.7\text{m}\Omega$, $Q_{GD} = 2 \text{ nC}$ and $\theta_{JA} \leq 96.6^\circ\text{C/W}$. An SO-8 MOSFET that meets the requirements is Vishay-Siliconix's Si4394DY; $BV_{DSS} = 30\text{V}$, $R_{DS(ON)} = 9.75\text{m}\Omega @ V_{GS} = 4.5\text{V}$, $Q_{GD} = 2.1\text{nC}$ and $\theta_{JA} = 90^\circ\text{C/W}$.

The bottom MOSFET has the requirements of $BV_{DSS} = 30\text{V}$ and $R_{DS(ON)} = 5.4\text{m}\Omega$. Vishay-Siliconix's Si4320DY meets the requirements; $BV_{DSS} = 30\text{V}$, $R_{DS(ON)} = 4\text{m}\Omega @ V_{GS} = 4.5\text{V}$.

Power Good

Power Good (PWRGD) is an open drain output that is pulled low when V_{OUT} is out-

side regulation. The PWRGD pin can be connected to VCC with an external 10K Ω resistor. During startup, output regulates when Soft Start (SS) reaches 0.8V (the reference voltage). PWRGD is enabled when SS reaches 1.6V. PWRGD output can be used as a "Power on Reset". The simplest way to adjust delay of the "Power on Reset" signal with respect to V_{OUT} in regulation is with the Soft Start Capacitor (C_{SS}) and is given by: $C_{SS} = (I_{SS} \cdot T_{delay}) / 0.8$ where I_{SS} is the Soft Start charge current (10 μA nominal).

Under Voltage Lock Out (UVLO)

The SP6136 has two separate UVLO comparators to monitor the bias (V_{CC}) and Input (V_{IN}) voltages independently. The V_{CC} UVLO is internally set to 4.25V. The V_{IN} UVLO is programmable through UVIN pin. When UVIN pin is greater than 2.5V the SP6136 is permitted to start up pending the removal of all other faults. A pair of internal resistors is connected to UVIN as shown in figure 4. Therefore without external biasing the V_{IN} start threshold is 9.5V. A small capacitor may be required between UVIN and GND to filter out noise. For applications with V_{IN} of 5V or 3.3V, connect UVIN directly to V_{IN} .

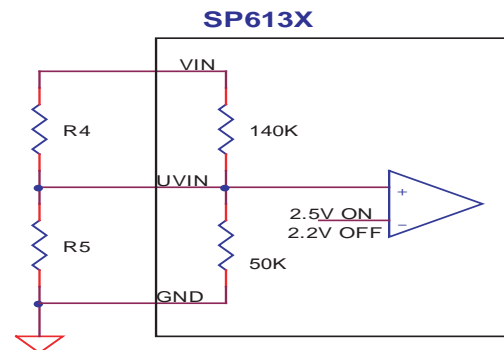

Figure 4- Internal and external bias of UVIN

To program the V_{IN} start threshold, use a pair of external resistors as shown. If external resistors are an order of magnitude smaller

than internal resistors, then the V_{IN} start threshold is given by:

$$V_{IN(start)} = 2.5 \cdot (R4+R5)/R5 \dots \dots \dots (8)$$

For example, if it is required to have a V_{IN} start threshold of 7V, then let $R5 = 5K\Omega$ and using equation (9) we get $R4 = 9.09K\Omega$.

Inductor Selection

There are many factors to consider in selecting the inductor including cost, efficiency, size and EMI. In a typical SP6136 circuit, the inductor is chosen primarily for value, saturation current and DC resistance. Increasing the inductor value will decrease output voltage ripple, but degrade transient response. Low inductor values provide the smallest size, but cause large ripple currents, poor efficiency and need more output capacitance to smooth out the larger ripple current. The inductor must also be able to handle the peak current at the switching frequency without saturating, and the copper resistance in the winding should be kept as low as possible to minimize resistive power loss. A good compromise between size, loss and cost is to set the inductor ripple current to be within 20% to 40% of the maximum output current.

The switching frequency and the inductor operating point determine the inductor value as follows:

$$L = \frac{V_{OUT} \cdot (V_{IN(MAX)} - V_{OUT})}{V_{IN(MAX)} \cdot F_s \cdot K_R \cdot I_{OUT(MAX)}}$$

where:

F_s = switching frequency

K_R = ratio of the ac inductor ripple current to the maximum output current

The peak to peak inductor ripple current is:

$$I_{PP} = \frac{V_{OUT} \cdot (V_{IN(MAX)} - V_{OUT})}{V_{IN(MAX)} \cdot F_s \cdot L}$$

Once the required inductor value is selected, the proper selection of core material is based on peak inductor current and efficiency requirements. The core must be large enough not to saturate at the peak inductor current

$$I_{PEAK} = I_{OUT(MAX)} + I_{PP}/2$$

and provide low core loss at the high switching frequency. Low cost powdered iron cores have a gradual saturation characteristic but can introduce considerable AC core loss, especially when the inductor value is relatively low and the ripple current is high. Ferrite materials, on the other hand, are more expensive and have an abrupt saturation characteristic with the inductance dropping sharply when the peak design current is exceeded. Nevertheless, they are preferred at high switching frequencies because they present very low core loss and the design only needs to prevent saturation. In general, ferrite or molypermalloy materials are the better choice for all but the most cost sensitive applications.

The power dissipated in the inductor is equal to the sum of the core and copper losses. To minimize copper losses, the winding resistance needs to be minimized, but this usually comes at the expense of a larger inductor. Core losses have a more significant contribution at low output current where the copper losses are at a minimum, and can typically be neglected at higher output currents where the copper losses dominate. Core loss information is usually available from the magnetic vendor.

The copper loss in the inductor can be calculated using the following equation:

$$P_{L(CU)} = I_{L(RMS)}^2 \cdot R_{WINDING}$$

where $I_{L(RMS)}$ is the RMS inductor current that can be calculated as follows:

$$I_{L(RMS)} =$$

$$I_{OUT(MAX)} \times \sqrt{1 + \frac{1}{3} \cdot \left\{ \frac{I_{PP}}{I_{OUT(MAX)}} \right\}^2}$$

Output Capacitor Selection

The required ESR (Equivalent Series Resistance) and capacitance drive the selection of the type and quantity of the output capacitors. The ESR must be small enough that both the resistive voltage deviation due to a step change in the load current and the output ripple voltage do not exceed the tolerance limits expected on the output voltage. During an output load transient, the output capacitor must supply all the additional current demanded by the load until the SP6136 adjusts the inductor current to the new value.

Therefore, the capacitance must be large enough so that the output voltage is held up while the inductor current ramps up or down to the value corresponding to the new load current. Additionally, the ESR in the output capacitor causes a step in the output voltage equal to the current. Because of the fast transient response and inherent 100% and 0% duty cycle capability provided by the SP6136 when exposed to output load transients, the output capacitor is typically chosen for ESR, not for capacitance value.

The output capacitor's ESR, combined with the inductor ripple current, is typically the main contributor to output voltage ripple. The maximum allowable ESR required to maintain a specified output voltage ripple can be calculated by:

$$R_{ESR} \leq \frac{\Delta V_{OUT}}{I_{PK-PK}}$$

where:

ΔV_{OUT} = Peak to Peak Output Voltage Ripple

I_{PK-PK} = Peak to Peak Inductor Ripple Current

The total output ripple is a combination of the ESR and the output capacitance value and can be calculated as follows:

$$\Delta V_{OUT} =$$

$$\sqrt{(I_{PP} \cdot R_{ESR})^2 + \left\{ \frac{I_{PP} \cdot (1-D)}{C_{OUT} \cdot F_s} \right\}^2}$$

where:

F_s = Switching Frequency

D = Duty Cycle

C_{OUT} = Output Capacitance Value

Input Capacitor Selection

The input capacitor should be selected for ripple current rating, capacitance and voltage rating. The input capacitor must meet the ripple current requirement imposed by the switching current. In continuous conduction mode, the source current of the high-side MOSFET is approximately a square wave of duty cycle V_{OUT}/V_{IN} . Most of this current is supplied by the input bypass capacitors. The RMS value of input capacitor current is determined at the maximum output current and under the assumption that the peak to peak inductor ripple current is low, it is given by:

$$I_{CIN(RMS)} = I_{OUT(MAX)} \times \sqrt{D \cdot (1-D)}$$

Schottky Diode Selection

When paralleled with the bottom MOSFET, an optional Schottky diode can improve efficiency and reduce noise. Without this Schottky diode, the body diode of the bottom MOSFET conducts the current during the non-overlap time when both MOSFETs are turned off. Unfortunately, the body di-

ode has high forward voltage and reverse recovery problems. The reverse recovery of the body diode causes additional switching noise when the diode turns off. The Schottky diode alleviates these sources of noise and additionally improves efficiency thanks to its low forward voltage. The reverse voltage across the diode is equal to input voltage, and the diode must be able to handle the peak current equal to the maximum load current.

The power dissipation of the Schottky diode is determined by:

$$P_{\text{DIODE}} = 2 \cdot V_F \cdot I_{\text{OUT}} \cdot T_{\text{NOL}} \cdot F_S$$

where:

T_{NOL} = non-overlap time between GH and GL.

V_F = forward voltage of the Schottky diode.

Loop Compensation Design

The open loop gain of the whole system can be divided into the gain of the error amplifier, PWM modulator, buck converter output stage, and feedback resistor divider. In order to cross over at the selected frequency FCO, the gain of the error amplifier has to compensate for the attenuation caused by the rest of the loop at this frequency.

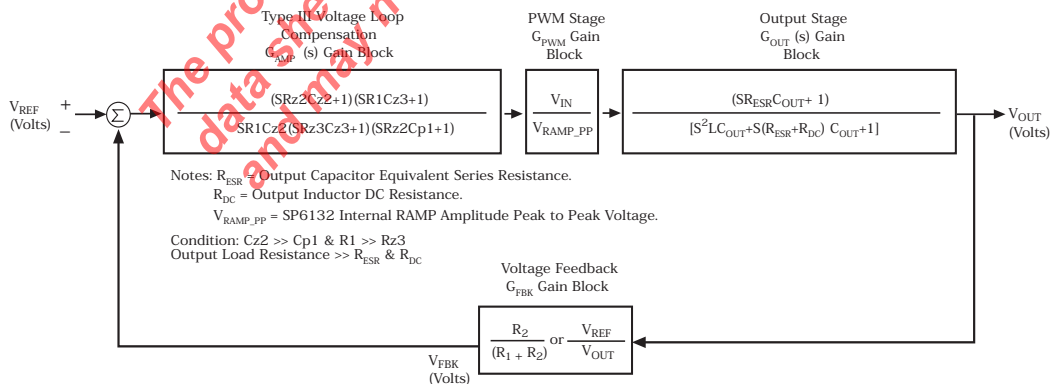

The goal of loop compensation is to manipulate loop frequency response such that its gain crosses over 0db at a slope of -20db/dec. The first step of compensation design is to pick the loop crossover frequency. High crossover frequency is desirable for fast transient response, but often jeopardizes the system stability. Crossover frequency should be higher than the ESR zero but less than 1/5 of the switching frequency. The ESR zero is contributed by the ESR associated with the output capacitors and can be determined by:

$$f_{Z(\text{ESR})} = \frac{1}{2\pi \cdot C_{\text{OUT}} \cdot \text{RESR}}$$

The next step is to calculate the complex conjugate poles contributed by the LC output filter,

$$f_{P(\text{LC})} = \frac{1}{2\pi \cdot \sqrt{L \cdot C_{\text{OUT}}}}$$

When the output capacitors are of a Ceramic Type, the SP6136 Evaluation Board requires a Type III compensation circuit to give a phase boost of 180° in order to counteract the effects of an under damped resonance of the output filter at the double pole frequency.

Definitions:

RESR = Output Capacitor Equivalent Series Resistance

R_{DC} = Output Inductor DC Resistance

$V_{\text{RAMP_PP}}$ = SP6136 internal RAMP Amplitude Peak to Peak Voltage
